

High-Side Variable Gain Current Sense Amplifier

Features

- High-Side Unidirectional Current Sense Amplifier
- Wide Common-Mode Input Range: 3 V to 60 V
- Wide Supply Voltage Range: 3 V to 60 V
- Independent Supply and Input Voltages
- Variable Gain Set by Single Resistor
- Low Quiescent Current: 50 μ A (Typical)
- Wide Temperature Range: -40°C to 125°C
- SOT23-5 Package

Applications

- Current Measurement
 - Monitors, Computers
- Telecom Equipment
- Power Management
- Servers

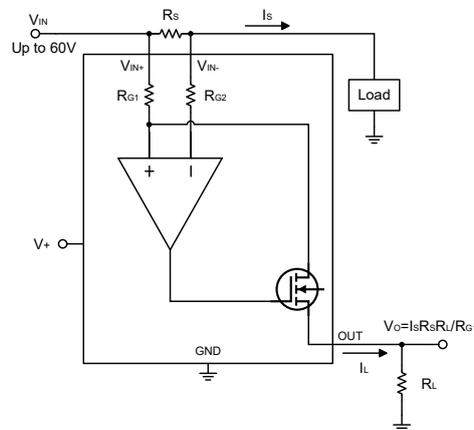

Description

The TPA127/TPA127B is a high-side, unidirectional current-sensing amplifier with a current output. Although designed for current shunt measurement, the device is also well suited for measurement and level conversion in creative applications.

The device converts the differential input voltage to a current output by its transconductance characteristic. The output current flows through the external load resistor and generates the output voltage. The gain between the output voltage and differential input voltage can be set from 1 to over 100 by the product of the external load resistor and transconductance.

The supply and input voltages are independent and operate from 3 V to 60 V. The device is available in the SOT23-5 package. Its operating temperature range is from -40°C to $+125^{\circ}\text{C}$.

Detailed Description

Overview

The TPA127/TPA127B device is a high-side, unipolar current-sensing amplifier with a current output. The supply voltage and input voltage are independent and can operate from 3 V to 60 V. The device can work normally even if the input voltage exceeds the supply voltage. Considering the minimum input voltage requirements, the TPA127/TPA127B is suitable for high-side current-sensing applications.

Functional Block Diagram

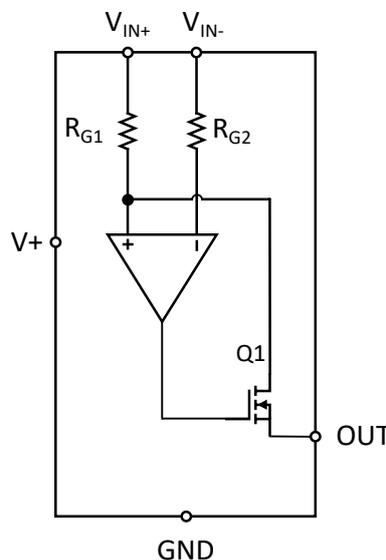

Figure 20. Functional Block Diagram

Feature Description

Output Range

The output voltage keeps linear in the specified range of the differential input voltage and the load resistor. When the differential input voltage is beyond the linear range, the output voltage reaches the maximum value. The maximum output voltage is limited by V_{IN+} and the power supply voltage. The relationship between maximum output voltage ($V_{out\ max}$) and V_{IN+} , $V+$ depends on either [Equation 1](#) or [Equation 2](#), whichever is lower.

$$V_{out\ max} = (V+) + 0.7\ V \quad (1)$$

$$V_{out\ max} = V_{IN+} \quad (2)$$

Bandwidth

The bandwidth is related to the load resistor. Increase the load resistor to acquire higher gain, which means lower bandwidth. There are several bandwidth curves in different load resistors in [Figure 1](#) and [Typical Performance Characteristics](#). Note that the parasitic capacitance parallel to the load resistor forms a pole with the load resistor in frequency characteristics, which means bandwidth loss. Keep the parasitic capacitance low to get no loss in bandwidth.

Application and Implementation

Note

Information in the following application sections is not part of the 3PEAK's component specification and 3PEAK does not warrant its accuracy or completeness. 3PEAK's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

Application Information

Operation

The TPA127/TPA127B internal circuit is shown in Figure 21. The load current in applications flows through the shunt resistor and forms a voltage drop as the differential input voltage (V_{dm}) to the chip. V_{dm} is delivered to the voltage on R_{G1} (V_{RG1}) by the TPA127/TPA127B, causing a current flowing into the MOSFET. The load resistor converts this current to output voltage.

$$I_S \cdot R_S = V_{IN+} - V_{IN-} \tag{3}$$

$$I_L = \frac{V_{IN+} - V_{IN-}}{R_{G1}} = g_m \cdot (V_{IN+} - V_{IN-}) \tag{4}$$

Where $g_m = 1 / R_{G1}$:

- TPA127: $g_m = 200 \mu A/V$
- TPA127B: $g_m = 1000 \mu A/V$

The output voltage is shown in Equation 5.

$$V_{out} = I_L \cdot R_L = g_m \cdot (I_S \cdot R_S) \cdot R_L \tag{5}$$

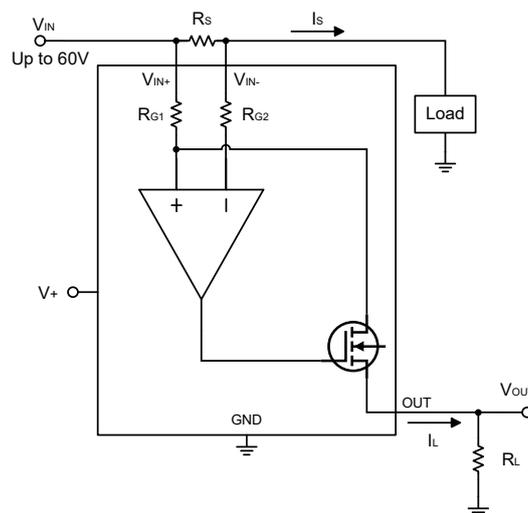

Figure 21. Internal Circuits

Typical Application

Figure 22 shows the typical application schematic.

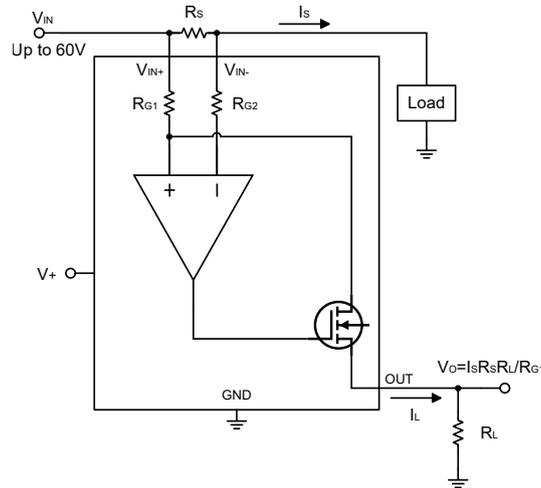

Figure 22. Typical Application Circuit

Output Voltage Detection

An analog-to-digital converter (ADC) is commonly used in output voltage detections. The input impedance of ADCs is parallel to the load resistor. Considering that the output voltage is vulnerable to the load impedance, the effect of the input impedance of ADCs on the output voltage is not negligible. To eliminate such influence on the output voltage, a buffer between the ADCs input and load resistor is added to isolate these two parts. The connection between the TPA127/TPA127B output and ADC is shown in Figure 23. If the output signal needs filtering, a capacitor is parallel to the load resistor to get an RC filter. The cut-off frequency is $1 / (2\pi R_L C_L)$

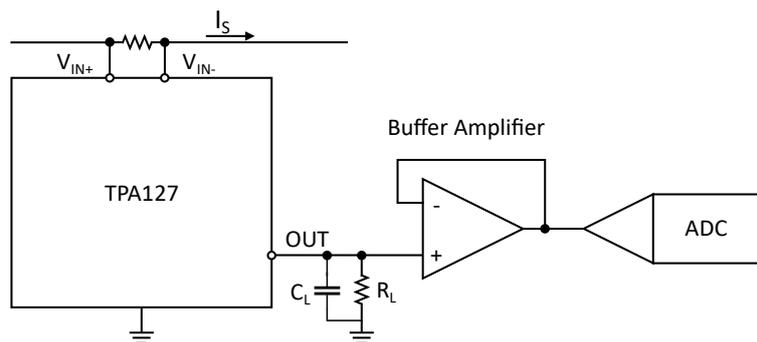

Figure 23. Buffer Output

Offsetting the Output Voltage

Some current sense amplifiers with the REF pin are used to set reference voltage. The TPA127/TPA127B can realize such an offset function by a voltage divider on the output. Figure 24 illustrates the offset function circuit. The output voltage fluctuates above the offset voltage.

The offset voltage is shown below.

High-Side Variable Gain Current Sense Amplifier

$$V_{\text{offset}} = V_B \cdot \frac{R_2}{R_1 + R_2} \tag{6}$$

The equivalent load resistor is R_1 parallel to R_2 . The output voltage is determined as below.

$$V_{\text{out}} = I_L \cdot R_L + V_{\text{offset}} = I_L \cdot \frac{R_1 R_2}{R_1 + R_2} + V_B \cdot \frac{R_2}{R_1 + R_2} \tag{7}$$

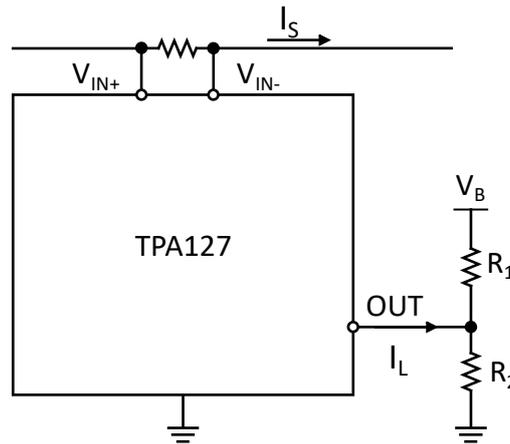

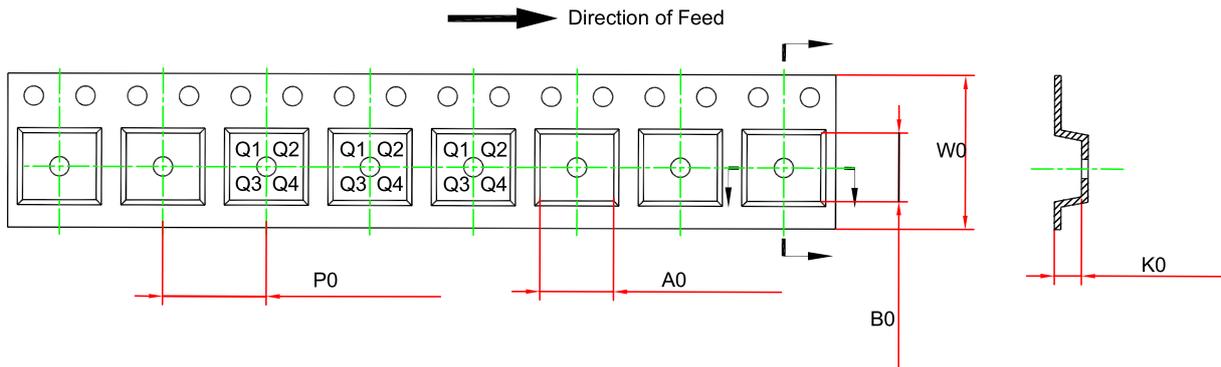

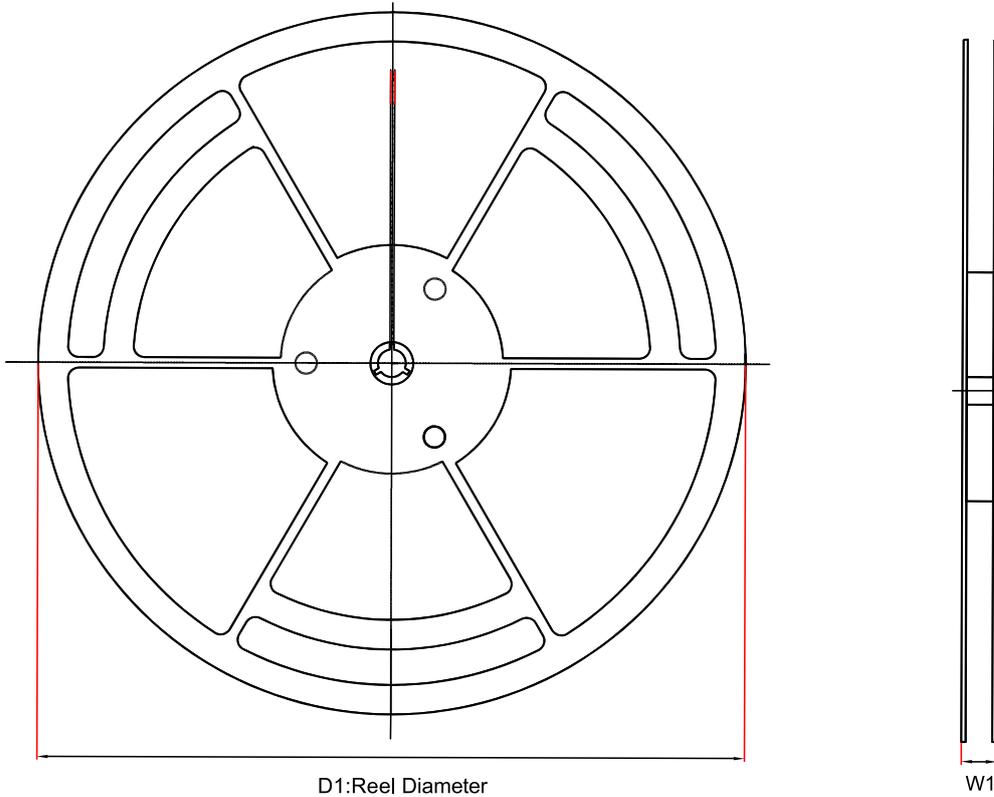

Figure 24. Offset Circuits

Power Supply Recommendations

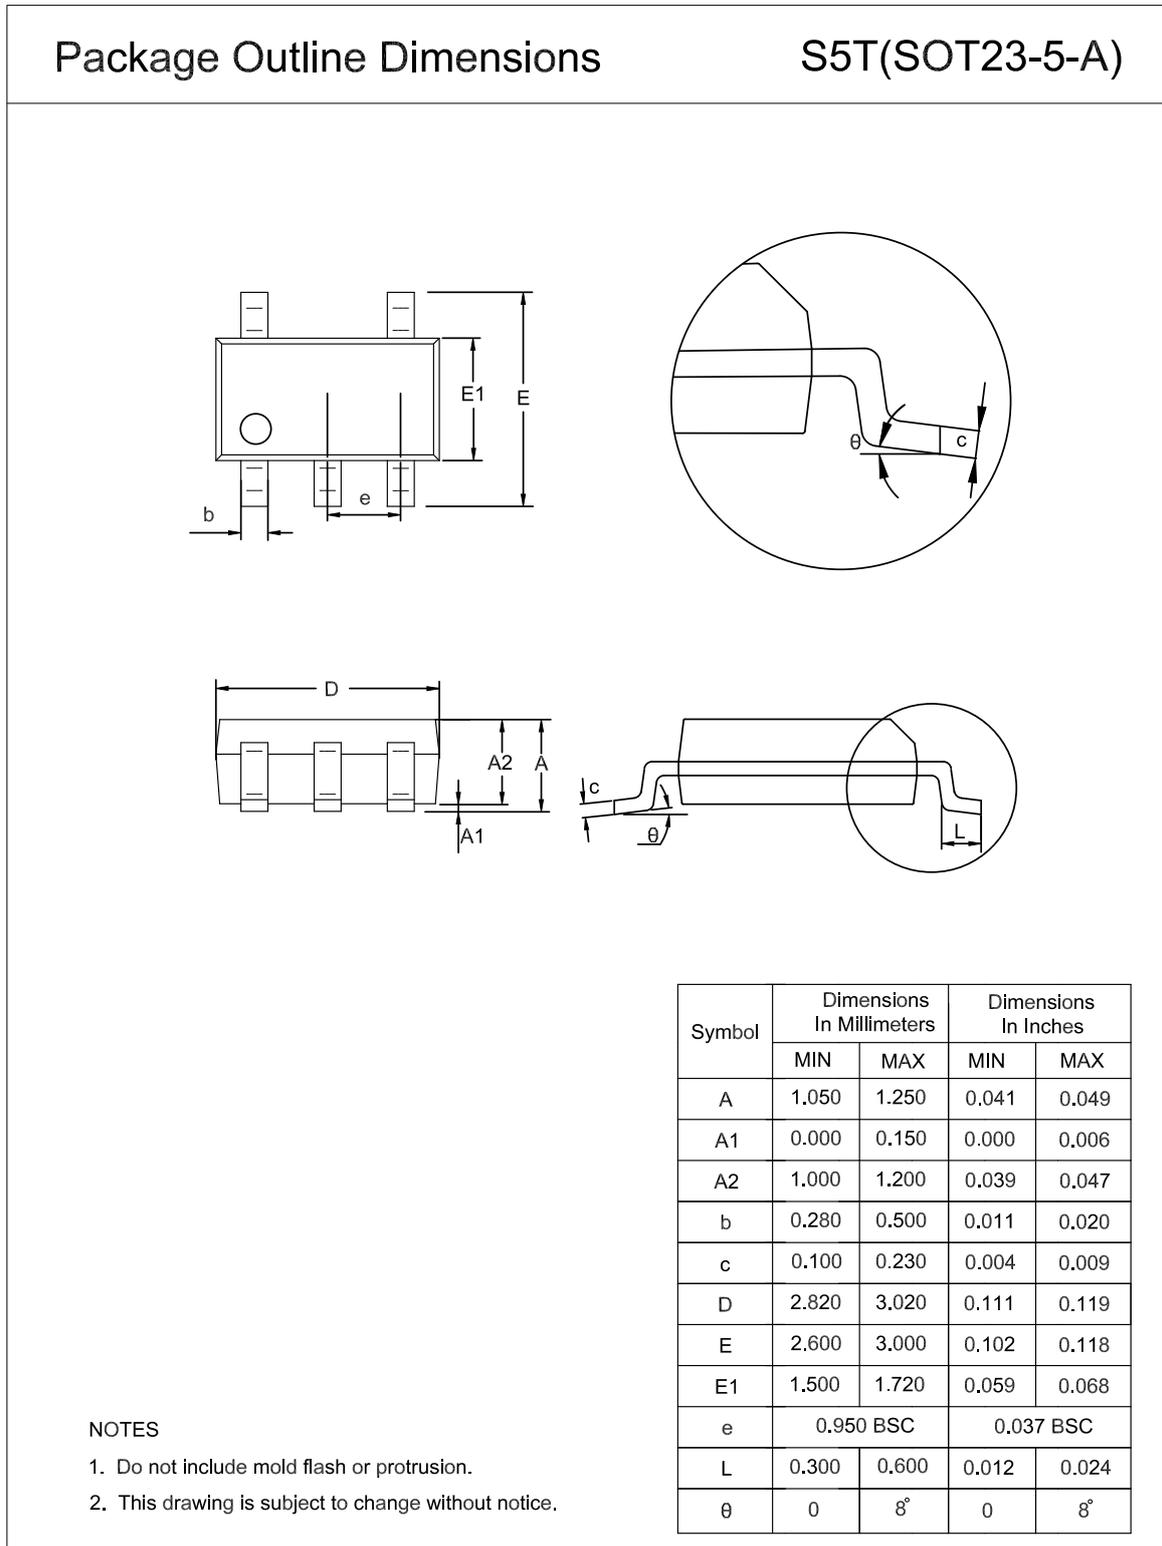

To realize better noise decoupling performance on the power supply, the power supply bypass capacitor is placed as close as possible to the supply and the ground terminal. A 0.1- μ F capacitor is recommended to use. Additional bypass capacitors can get better noise suppression on the power supply.
